Suppose we start at a point  $\zeta$  in the interior of a located subset  $C$  of a normed space  $X$  and move linearly towards a point  $z$  in the metric complement of  $C$ . Are we able to tell when we are crossing the boundary of  $C$ ?

In general, the constructive answer is *no*.

However, our geometric intuition suggests that when  $C$  is convex, we might succeed in pinpointing boundary crossing points.

Our context is a normed space  $X$ . Note that if  $x, y \in X$ , then  $x \neq y$  ( $x$  and  $y$  are **distinct**) means  $\|x - y\| > 0$ .

A subset  $C$  of  $X$  has three types of complement:

- the **logical complement**

$$\neg C = \{x \in X : \forall y \in C \neg(x = y)\},$$

Our context is a normed space  $X$ . Note that if  $x, y \in X$ , then  $x \neq y$  ( $x$  and  $y$  are **distinct**) means  $\|x - y\| > 0$ .

A subset  $C$  of  $X$  has three types of complement:

- the **logical complement**

$$\neg C = \{x \in X : \forall y \in C \neg(x = y)\},$$

- the **complement**

$$\sim C = \{x \in X : \forall y \in C (x \neq y)\},$$

Our context is a normed space  $X$ . Note that if  $x, y \in X$ , then  $x \neq y$  ( $x$  and  $y$  are **distinct**) means  $\|x - y\| > 0$ .

A subset  $C$  of  $X$  has three types of complement:

- the **logical complement**

$$\neg C = \{x \in X : \forall_{y \in C} \neg(x = y)\},$$

- the **complement**

$$\sim C = \{x \in X : \forall_{y \in C} (x \neq y)\},$$

- the **metric/apartness complement**

$$-C = \{x \in X : \exists_{r>0} \forall_{y \in C} (\|x - y\| \geq r)\}$$

Our boundary-crossing theorem uses three geometric lemmas about convexity.

**Lemma 1** *Let  $C$  be a convex subset of  $X$ ,  $\zeta$  an interior point of  $C$ , and  $r$  a positive number such that  $B(\zeta, r) \subset C$ . Let  $z \neq \zeta$ , and let  $z' = t\zeta + (1-t)z$  where  $0 < t < 1$ . If  $B(z, tr)$  intersects  $C$ , then  $B(z', t^2r) \subset C$ .*

Our boundary-crossing theorem uses three geometric lemmas about convexity.

**Lemma 1** *Let  $C$  be a convex subset of  $X$ ,  $\xi$  an interior point of  $C$ , and  $r$  a positive number such that  $B(\xi, r) \subset C$ . Let  $z \neq \xi$ , and let  $z' = t\xi + (1-t)z$  where  $0 < t < 1$ . If  $B(z, tr)$  intersects  $C$ , then  $B(z', t^2r) \subset C$ .*

**Lemma 2** *Let  $C$  be an open convex subset of  $X$  such that  $C \cup -C$  is dense in  $X$ . Let  $\xi \in C$  and  $z \in -C$ . Then  $(C \cup -C) \cap [\xi, z]$  is dense in  $[\xi, z]$ .*

The third lemma is almost trivial, yet remarkably useful.

**Lemma 3** *Let  $x_1, x_2$  be distinct points of  $X$ ; let  $x_3 = \lambda x_1 + (1 - \lambda)x_2$  with  $\lambda \neq 0, 1$ . For all  $\alpha, \beta > 0$ , if  $\|x - x_1\| < \alpha / |\lambda|$  and  $\|y - x_2\| < \beta / |1 - \lambda|$ , then*

$$\|\lambda x + (1 - \lambda)y - x_3\| < \alpha + \beta.$$

The third lemma is almost trivial, yet remarkably useful.

**Lemma 3** *Let  $x_1, x_2$  be distinct points of  $X$ ; let  $x_3 = \lambda x_1 + (1 - \lambda)x_2$  with  $\lambda \neq 0, 1$ . For all  $\alpha, \beta > 0$ , if  $\|x - x_1\| < \alpha/|\lambda|$  and  $\|y - x_2\| < \beta/|1 - \lambda|$ , then*

$$\|\lambda x + (1 - \lambda)y - x_3\| < \alpha + \beta.$$

One application:

**Proposition 1** *If  $C$  is an inhabited open convex subset of  $X$ , then  $-C$  is dense in  $\sim C$ .*

A more significant application of Lemma 3 is in the proof of our boundary crossing theorem:

**Theorem 1** *Let  $C$  be an open convex subset of a Banach space  $X$ , such that  $C \cup -C$  is dense in  $X$ , and let  $\xi \in C$ . For each  $z \in -C$  and each  $t \in [0, 1]$  write*

$$z_t = t\xi + (1 - t)z.$$

*Then the following hold:*

- (a)  $\gamma(\xi, z) = \inf\{t \in [0, 1] : z_t \in C\}$  exists, and  $0 < \gamma(\xi, z) < 1$ .
- (b)  $z_{\gamma(\xi, z)}$  is the unique intersection of  $[\xi, z]$  with the boundary  $\partial C$  of  $C$ .
- (c) If  $\gamma(\xi, z) < t \leq 1$ , then  $z_t \in C$ .
- (d) If  $0 \leq t < \gamma(\xi, z)$ , then  $z_t \in -C$ .

Moreover, the boundary crossing map  $(\xi, z) \rightsquigarrow z_{\gamma(\xi, z)}$  of  $C \times -C$  into  $\partial C$  is continuous.

A subset  $C$  of a vector space  $X$  over  $\mathbf{K}$  is called a **cone** if for all  $x, y \in C$  and all  $t > 0$ , both  $x + y$  and  $tx$  belong to  $C$ . In that case,  $C$  is convex.

The closure of a cone is a cone, as is the intersection of two cones.

A subset  $C$  of a vector space  $X$  over  $\mathbf{K}$  is called a **cone** if for all  $x, y \in C$  and all  $t > 0$ , both  $x + y$  and  $tx$  belong to  $C$ . In that case,  $C$  is convex.

The closure of a cone is a cone, as is the intersection of two cones.

If  $K$  is a convex subset of  $X$ , then the set

$$c(K) = \{tx : x \in K, t > 0\}$$

is a cone—the **cone generated by the convex set  $K$** .

If  $X$  is a normed space and  $K$  is open, then so is  $c(K)$ .

**Lemma 4** *Let  $K$  be a bounded, located, convex subset of a normed space  $X$  such that  $\rho(0, K) > 0$ . Then  $c(K)$  is located.*

**Lemma 4** *Let  $K$  be a bounded, located, convex subset of a normed space  $X$  such that  $\rho(0, K) > 0$ . Then  $c(K)$  is located.*

**Proof.** Given  $x_0 \in X$ , for all  $x \in X$  and  $t > 0$  we have

$$\|x_0 - tx\| \geq t\|x\| - \|x_0\|,$$

so

$$\rho(x_0, tK) \geq t\rho(0, K) - \|x_0\| \rightarrow \infty \text{ as } t \rightarrow \infty.$$

We can therefore find  $\tau > 0$  such that

$$\rho(x_0, c(K)) = \rho(x_0, \tau K). \quad \square$$

**Lemma 5** *Let  $K$  and  $L$  be open cones in a normed space  $X$  such that  $K \cup L$  is dense in  $X$  and  $K \subset \sim L$ . Then*

- (i)  $K \subset -L$  and  $L \subset -K$ ,
- (ii)  $K \cup -K$  and  $L \cup -L$  are dense in  $X$ , and
- (iii)  $K$  and  $L$  have a common boundary—namely,  $\overline{K} \cap \overline{L}$ .

*If also  $L = \{-x : x \in K\}$ , then  $\partial K$  is a subspace of  $X$ .*

By a **half-space** of a normed space  $X$  we mean a convex subset  $K$  such that  $\partial K$  is a hyperplane and the set

$$\{x \in X : x \in K \vee -x \in K\}$$

is dense in  $X$ .

By a **half-space** of a normed space  $X$  we mean a convex subset  $K$  such that  $\partial K$  is a hyperplane and the set

$$\{x \in X : x \in K \vee -x \in K\}$$

is dense in  $X$ .

The **Basic Separation Theorem**:

**Theorem 2** *Let  $X$  be a separable normed space,  $K_0$  a bounded, located, open, convex subset of  $X$  such that  $\rho(0, K_0) > 0$ , and  $x_0$  a point of  $X$  such that  $-x_0 \in K_0$ . Then there exists an open half-space  $K$  of  $X$  such that  $K_0 \subset K$ ,  $\rho(x_0, K) > 0$ , and the boundary of  $K$  is a located subspace of  $X$  that is a hyperplane with associated vector  $x_0$ .*

The (full) **Separation Theorem**:

**Theorem 3** *Let  $A$  and  $B$  be bounded convex subsets of a separable normed space  $X$  such that the **algebraic difference***

$$\{y - x : x \in A, y \in B\}$$

*is located and the **mutual distance***

$$d = \inf \{\|y - x\| : x \in A, y \in B\}$$

*is positive. Then for each  $\varepsilon > 0$  there exists a normed linear functional  $u$  on  $X$ , with norm 1, such that*

$$\operatorname{Re} u(y) > \operatorname{Re} u(x) + d - \varepsilon \quad (x \in A, y \in B).$$

## The Berger-Svindland Separation Theorem:

**Theorem 4** *Let  $C, Y$  be convex subsets of  $\mathbf{R}^n$  such that*

- (i)  *$C$  is convex and compact;*
- (ii)  *$Y$  is convex, closed, and located;*
- (iii)  *$x \neq y$  for all  $x \in C$  and  $y \in Y$ .*

*Then there exist  $p \in \mathbf{R}^n$  and real  $\alpha, \beta$  such that*

$$\langle p, x \rangle < \alpha < \beta < \langle p, y \rangle$$

*for all  $x \in C$  and  $y \in Y$ .*

A crucial step in the proof is showing that

$$\inf\{\|x - y\| : x \in C, y \in Y\} > 0. \quad (1)$$

Under what conditions can we show that if  $C, Y$  are located convex subsets of a normed space satisfying (iii), then (1) holds?

Recall the following:

- ▶ **Bishop's Lemma:** if  $Y$  is an inhabited, complete, located subset of a metric space  $X$ , then for each  $x \in X$  such that  $x \neq y$  implies that  $\rho(x, Y) > 0$ .

Recall the following:

- ▶ **Bishop's Lemma:** if  $Y$  is an inhabited, complete, located subset of a metric space  $X$ , then for each  $x \in X$  such that  $x \neq y$  implies that  $\rho(x, Y) > 0$ .
- ▶ A convex subset  $C$  of a normed space  $X$  is **uniformly rotund** if for each  $\varepsilon > 0$  there exists  $\delta > 0$  such that if  $x, x' \in C$  and  $\|x - x'\| > \varepsilon$ , then  $\frac{1}{2}(x + x') + z \in C$  for all  $z \in X$  with  $\|z\| \leq \delta$ .

We now have a weak generalisation of Bishop's Lemma.

**Theorem 5** *Let  $K, L$  be inhabited, complete convex subsets of a normed space  $X$  such that*

- (a)  *$K$  is uniformly rotund,*
- (b)  *$L$  contains at least two distinct points, and*
- (c)  *$d \equiv \inf_{x \in K} \rho(x, L)$  exists.*

*Then there exist  $x_\infty \in K$  and  $y_\infty \in L$  such that if  $x_\infty \neq y_\infty$ , then  $d$  is positive.*

Theorem 5 is at least interesting, and perhaps useful.

But we should note that if  $K$  is compact and contains at least two distinct points, then, by uniform rotundity,  $K$  includes a ball centred at their midpoint; that ball, being closed and located in  $K$ , is compact, so the space  $X$  is finite-dimensional.
